

## Occurrence Details

**Occurrence Number:** 105L 054

**Occurrence Name:** Kal

**Occurrence Type:** Hard-rock

**Status:** Prospect

**Date printed:** 6/16/2025 2:13:18 PM

## General Information

**Primary Commodities:** barium

**Secondary Commodities:** gold, lead, silver, zinc

**Deposit Type(s):** Sediment hosted Stratiform Barite

**Location(s):** 62°54'12" N - -135°15'20" W

**NTS Mapsheet(s):** 105L14

**Location Comments:** .5 Kilometres

**Hand Samples Available:** No

**Last Reviewed:**

## Capsule

### Work History

Staked as part of Kal cl 1-292 (YA43615) between April to Sep/81 by Anaconda Canada Exploration Ltd following an airborne magnetometer and EM surveying. The company staked Bum cl 1-32 (YA43696) adjoining the northwest corner of the Kal group in Apr/81. Anaconda carried out geological mapping, geochemical sampling and geophysical surveying of both claim groups in 1982 and added Bum cl 33-106 (YA76589) in July that year. Anaconda's interest was transferred to Fleck Minerals Inc in 1985, which allowed the Kal claims to lapse. The remaining Bum cl 1-32 were optioned to Dromedary Exploration Company Ltd in Jun/88.

Dromedary restaked the occurrence as DMC cl 1-18 (YB02749) in Sep/88 and carried out geological mapping, geochemical sampling and hand trenching before adding DMC cl 37-44 (YB02837) later that month. Dromedary also staked DMC cl 19-36 (YB02819) 5 km to the northwest at the same time (Minfile Occurrence #105L 037).

In Aug/93 the DMC claims were optioned to Energold Minerals Inc, which carried out auger sampling, magnetometer surveying and geological mapping that year.

In 1995 G. Carlson acquired 100% interest in the DMC claims from Fleck Minerals and in Jun/96 Carlson optioned the claims to Blackstone Resources Inc which carried out limited geochemical rock sampling that year. Blackstone staked DMC cl 37-155 (YB80838) in Jun/97 surrounding both of the original DMC claim groups forming one contiguous block of claims. In Jul/97 the company carried out geological mapping, prospecting and geochemical rock and soil sampling between the existing grid lines in the area.

### Capsule Geology

Sphalerite and argentiferous galena occur with pyrite, pyrrhotite and massive, nodular barite in fine-grained, hornfelsed turbidites of the lower Devonian to Mississippian Earn Group, which are thrust over calcareous muscovite phyllite/siltstone and wavy banded limestone of the Cambrian to Ordovician Ketchika Group. The Dromedary Mountain occurrence (Minfile Occurrence #105L 051), 27 km to the east, occurs at the same stratigraphic level.

The Kal showing consists of a mineralized horizon exposed in 12 trenches. Chip samples from trenches assayed up to 8.9% Pb, 2.8% Zn and 180 g/t Ag across 1 m. The neighboring Cave showing (Minfile Occurrence #105L 037) is exposed in a creek canyon 5 km to the northwest. A float boulder sampled in 1984 assayed 18.2% Zn, 0.64% Pb and 12.8 g/t Ag. Chip sampling in 1988 returned values up to 0.64% Pb, 18.17% Zn and 12.8 g/t Ag over 35 cm.

Regional soil sampling carried out in 1988 outlined coincident lead-zinc-silver anomalies which although discontinuous, extend over a strike length of 7.5 km and cover both the Kal and Cave showings. Within the 7.5 km anomalous area, further sampling with a hand auger in 1992 outlined a stronger 1 km long anomaly with values up to 5 728 ppm Pb. Samples from hand trench 92-1 located 550 m east-southeast of the Cave showing contained up to 7 395 ppm Pb and 4 504 ppm Zn over a 0.6 m interval of rusty weathering shale and siltstone.

Prospecting by Blackstone Resources in 1996 resulted in the discovery of a new Pb-Zn showing at the western edge of DMC cl 1-18 claims. The showing consists of interbedded shale, phyllite and calcareous siltstone that hosts pyrite, galena and sphalerite as stringers and laminations parallel to subparallel to the foliation. Barite occurs as nodules. One selective grab sample collected over a width of 50 cm returned values of 12.5% Pb, 4.70% Zn, 195 ppm Ag and 40 ppb Au.

Work in 1997 identified several zones of mineralized float and a new showing along the anomalous trend between the Kal and Cave showings that are characterized by iron sulfide mineralization, carbonate porphyroblasts, manganese oxide staining and hematitic weathering associated with fossiliferous strata. The Gully Showing, located about halfway between the Kal and Cave showings, returned up to 5.35% Pb and 5.83% Zn from grab sampling and 1.2% Pb and 0.6% Zn over 1.0 m from chip sampling.
