

## Occurrence Details

**Occurrence Number:** 1150 164  
**Occurrence Name:** Matgan  
**Occurrence Type:** Hard-rock  
**Status:** Prospect  
**Date printed:** 12/16/2025 3:19:37 PM

## General Information

**Secondary Commodities:** gold, palladium, platinum  
**Deposit Type(s):** Ultramafic Mafic Alaskan-type Pt+/-Os+/-Rh+/-Ir  
**Location(s):** 63°41'43" N - -139°1'23" W  
**NTS Mapsheet(s):** 115011  
**Location Comments:** .5 Kilometres  
**Hand Samples Available:** No  
**Last Reviewed:**

### Capsule

#### Work History

Staked as Dun cl 1-24 (YC20619) in March, 2001 by 19651 Yukon Inc., which staked Farm cl 1-6 (YC20613) to the north at the same time. The company carried out basic geological mapping, geochemical sampling, prospecting and magnetic and VLF geophysical surveys in the first half of 2002. In the latter half of the year the company dug trenches, carried out additional magnetic and VLF geophysical surveys, and drilled 6 auger drill holes (58.5 m).

In 2005, Klondike Star Mineral Corp. performed soil surveys across the property.

#### Capsule Geology

The occurrence is located at the northwest end of the Yukon portion of the Yukon Tanana terrane, on the south side of the Indian River. The area in general escaped glaciation, thus the occurrence is underlain by thick fluvial silt, sand and gravel deposits. The area located immediately south of the occurrence was remapped in 2001 by Ryan and Gordey (2002, 2003) as part of the ancient Pacific Margin NATMAP Project initiated by the Geological Survey of Canada, Yukon Geological Survey and British Columbia Geological Survey Branch. Mortensen (1996) mapped the area north of the Indian River, Lowey (1983) mapped the occurrence and surrounding area, and Bostock (1942) mapped the entire Ogilvie map sheet (1150 and 115N).

Employing Bostock and Lowey's early work and extrapolating Ryan and Gordey's work, it is likely that the occurrence area is underlain by Devonian to Mississippian siliclastic metasedimentary rocks. The metasedimentary rocks are likely interstratified with amphibolite rocks that represent volcanic piles built up on the siliclastic foundation. Orthogneiss rocks, derived from tonalite and diorite sheets, likely intrude the volcanic piles represented by the amphibolite rocks. Evidence of this can be observed about 1 km southwest of the occurrence where Ryan and Gordey mapped grey gneiss. The sequence may or may not include felsic to intermediate orthogneiss, composed of pink to orange, weathered granite to granodiorite sheets and veinlets that crosscut the diorite and tonalite sheets with which they were transported.

Cretaceous clastic and volcanic rocks probably unconformably overlie the previously described sequence (Bostock, Lowey, Ryan and Gordey). The lower part is a succession of interbedded sandstone, shale, conglomerate and minor coral which is correlated with the Tantalus Formation. This is in turn overlain by voluminous basalt and andesite flows assigned to the lower Carmacks Group. Large tracts of both units flank Haystack Mountains, located due west of the occurrence. The conglomerates are known to carry gold and several occurrences in the area have been explored for their paleoplacer gold potential.

The occurrence marks the location of a small ultramafic intrusion. Both Bostock and Lowey noted its presence on their respective maps. Prospecting identified an outcrop containing green, dark brown weathering dunite. Morgan et al., felt that the intrusion might represent a potential Alaska Type ultramafic platinum group element (PGE) deposit. A regional airborne magnetic survey (Shives, 2001), jointly funded by the Geological Survey of Canada and the Yukon Geology Program, identified a magnetic high over the intrusion.

Rock sampling in early 2002 returned values of up to 0.12 g/t palladium, 1,669 ppm nickel, 987 ppm chromium, 972 ppm manganese, and 12 wt% magnesium. The ground magnetic/gradient survey identified numerous magnetic and gradient anomalies within the larger airborne magnetic survey. The two highest magnetic anomalies were hand trenched and sampled. One trench, located in the south central end of the intrusion, returned 24 ppb platinum and 13 ppb palladium over 1 metre.

The six auger drill holes were collared across Bishop Creek in the middle of the intrusion and in the most deeply eroded section of the dunite body. None of the holes intersected anomalous platinum group elements (PGE), but a composite sample comprised of longtom concentrates from 3 holes returned 204 ppb gold.

Soil sampling in 2005 returned up to 50.5 ppb Au, platinum and palladium were not mentioned in the results.

### Work History

Date	Work Type	Comment
12/31/2002	Geochemistry	
12/31/2002	Geology	
12/31/2002	Drilling	Six holes, 58.5 m.
12/31/2002	Ground Geophysics	Also VLF-EM survey.
12/31/2002	Trenching	

12/31/2001	Other	Preliminary prospecting carried out at time of staking.
